 The IS-LM model is by far the most popular pedagogical and policy tool in macroeconomics since its first formulation (Hicks, 1937; Modigliani, 1944).

 The IS-LM only facilitates comparative statics exercises, allowing the identification of the new equilibrium position following a shock but not the trajectory followed by the economy. No dynamics.

- General equilibrium condition derived by intersecting a flow curve (the IS) with a stock curve (the LM).
